# Econ 219A <br> Psychology and Economics: Foundations 

(Lecture 5)

Stefano DellaVigna

April 2, 2014

Outline

1. Reference Dependence: Labor Supply
2. Reference Dependence: Disposition Effect
3. Reference Dependence: Equity Premium
4. Reference Dependence: Domestic Violence
5. Reference Dependence: Insurance

## 1 Reference Dependence: Labor Supply

- Does reference dependence affect work/leisure decision?
- Framework:
- effort $h$ (no. of hours)
- hourly wage $w$
- Returns of effort: $Y=w * h$
- Linear utility $U(Y)=Y$
- Cost of effort $c(h)=\theta h^{2} / 2$ convex within a day
- Standard model: Agents maximize

$$
U(Y)-c(h)=w h-\frac{\theta h^{2}}{2}
$$

- (Assumption that each day is orthogonal to other days - see below)
- Reference dependence: Threshold $T$ of earnings agent wants to achieve
- Loss aversion for outcomes below threshold:

$$
U=\left\{\begin{array}{cc}
w h-T & \text { if } \quad w h \geq T \\
\lambda(w h-T) & \text { if } \quad w h<T
\end{array}\right.
$$

with $\lambda>1$ loss aversion coefficient

- Referent-dependent agent maximizes

$$
\begin{array}{cl}
w h-T-\frac{\theta h^{2}}{2} & \text { if } \quad h \geq T / w \\
\lambda(w h-T)-\frac{\theta h^{2}}{2} & \text { if } \quad h<T / w
\end{array}
$$

- Derivative with respect to $h$ :

$$
\begin{array}{ccc}
w-\theta h & \text { if } & h \geq T / w \\
\lambda w-\theta h & \text { if } & h<T / w
\end{array}
$$

1. Case $1(\lambda w-\theta T / w<0)$.

- Optimum at $h^{*}=\lambda w / \theta<T / w$

2. Case $2(\lambda w-\theta T / w>0>w-\theta T / w)$

- Optimum at $h^{*}=T / w$

3. Case $3(w-\theta T / w>0)$

- Optimum at $h^{*}=w / \theta>T / w$
- Standard theory $(\lambda=1)$.
- Interior maximum: $h^{*}=w / \theta$ (Cases 1 or 3$)$
- Labor supply
- Combine with labor demand: $h^{*}=a-b w$, with $a>0, b>0$.
- Optimum:

$$
L^{S}=w^{*} / \theta=a-b w^{*}=L^{D}
$$

or

$$
w^{*}=\frac{a}{b+1 / \theta}
$$

and

$$
h^{*}=\frac{a}{b \theta+1}
$$

- Comparative statics with respect to $a$ (labor demand shock): $a \uparrow->h^{*} \uparrow$ and $w^{*} \uparrow$
- On low-demand days (low w) work less hard -> Save effort for highdemand days
- Model with reference dependence $(\lambda>1)$ :
- Case 1 or 3 still exist
- BUT: Case 2. Kink at $h^{*}=T / w$ for $\lambda>1$
- Combine Labor supply with labor demand: $h^{*}=a-b w$, with $a>$ $0, b>0$.

Figure 1a

wage

- Case 2: Optimum:

$$
L^{S}=T / w^{*}=a-b w^{*}=L^{D}
$$

and

$$
w^{*}=\frac{a+\sqrt{a^{2}+4 T b}}{2 b}
$$

- Comparative statics with respect to $a$ (labor demand shock):
$-a \uparrow->h^{*} \uparrow$ and $w^{*} \uparrow($ Cases 1 or 3$)$
$-a \uparrow->h^{*} \downarrow$ and $w^{*} \uparrow$ (Case 2)
- Case 2: On low-demand days (low $w$ ) need to work harder to achieve reference point $T \rightarrow$ Work harder $->$ Opposite to standard theory
- (Neglected negligible wealth effects)

Camerer, Babcock, Loewenstein, and Thaler (QJE 1997)

- Data on daily labor supply of New York City cab drivers
- 70 Trip sheets, 13 drivers (TRIP data)
- 1044 summaries of trip sheets, 484 drivers, dates: $10 / 29-11 / 5,1990$ (TLC1)
- 712 summaries of trip sheets, $11 / 1-11 / 3,1988$ (TLC2)
- Notice data feature: Many drivers, few days in sample
- Analysis in paper neglects wealth effects: Higher wage today $->$ Higher lifetime income
- Justification:
- Correlation of wages across days close to zero
- Each day can be considered in isolation
- -> Wealth effects of wage changes are very small
- Test:
- Assume variation across days driven by $\Delta a$ (labor demand shifter)
- Do hours worked $h$ and $w$ co-vary negatively (standard model) or positively?
- Raw evidence

- Estimated Equation:

$$
\log \left(h_{i, t}\right)=\alpha+\beta \log \left(Y_{i, t} / h_{i, t}\right)+X_{i, t} \Gamma+\varepsilon_{i, t} .
$$

- Estimates of $\hat{\beta}$ :
$-\hat{\beta}=-.186$ (s.e. 129) - TRIP with driver f.e.
$-\hat{\beta}=-.618$ (s.e. .051) - TLC1 with driver f.e.
$-\hat{\beta}=-.355$ (s.e. .051) - TLC2
- Estimate is not consistent with prediction of standard model
- Indirect support for income targeting
- Issues with paper:
- Economic issue 1. Reference-dependent model does not predict (log-) linear, negative relation

Figure 1a

- What happens if reference income is stochastic? (Koszegi-Rabin, 2006)
- Econometric issue 1. Division bias in regressing hours on log wages
- Wages is not directly observed - Computed at $Y_{i, t} / h_{i, t}$
- Assume $h_{i, t}$ measured with noise: $\tilde{h}_{i, t}=h_{i, t} * \phi_{i, t}$. Then,

$$
\log \left(\tilde{h}_{i, t}\right)=\alpha+\beta \log \left(Y_{i, t} / \tilde{h}_{i, t}\right)+\varepsilon_{i, t} .
$$

becomes

$$
\log \left(h_{i, t}\right)+\log \left(\phi_{i, t}\right)=\alpha+\beta\left[\log \left(Y_{i, t}\right)-\log \left(h_{i, t}\right)\right]-\beta \log \left(\phi_{i, t}\right)+\varepsilon_{i, t}
$$

- Downward bias in estimate of $\hat{\beta}$
- Response: instrument wage using other workers' wage on same day
- IV Estimates:

TABLE III
IV Log Hours Worked Equations

| Sample | TRIP |  | TLC1 |  | TLC2 |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Log hourly wage | -.319 | .005 | -1.313 | -.926 | -.975 |
|  | $(.298)$ | $(.273)$ | $(.236)$ | $(.259)$ | $(.478)$ |
| High temperature | -.000 | -.001 | .002 | .002 | -.022 |
|  | $(.002)$ | $(.002)$ | $(.002)$ | $(.002)$ | $(.007)$ |

- Notice: First stage not very strong (and few days in sample)

|  | First-stage regressions |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Median | .316 | .026 | -.385 | -.276 | 1.292 |
|  | $(.225)$ | $(.188)$ | $(.394)$ | $(.467)$ | $(4.281)$ |
| 25th percentile | .323 | .287 | .693 | .469 | -.373 |
|  | $(.160)$ | $(.126)$ | $(.241)$ | $(.332)$ | $(3.516)$ |
| 75 th percentile | .399 | .289 | .614 | .688 | .479 |
|  | $(.171)$ | $(.149)$ | $(.242)$ | $. .292)$ | $(1.699)$ |
| Adjusted $R^{2}$ | .374 | .642 | .056 | .206 | .019 |
| $P$-value for $F$-test of | .000 | .004 | .000 | .000 | .020 |
| instruments for wage |  |  |  |  |  |

- Econometric issue 2. Are the authors really capturing demand shocks or supply shocks?
- Assume $\theta$ (disutility of effort) varies across days.
- Even in standard model we expect negative correlation of $h_{i, t}$ and $w_{i, t}$

-     - Camerer et al. argue for plausibility of shocks due to $a$ rather than $\theta$
- Farber (JPE, 2005)
- Re-Estimate Labor Supply of Cab Drivers on new data
- Address Econometric Issue 1
- Data:
- 244 trip sheets, 13 drivers, 6/1999-5/2000
- 349 trip sheets, 10 drivers, 6/2000-5/2001
- Daily summary not available (unlike in Camerer et al.)
- Notice: Few drivers, many days in sample
- First, replication of Camerer et al. (1997)

TABLE 3

| Labor Supply Function Estimates: OLS Regression of Log Hours |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
| Variable | $(1)$ | $(2)$ | $(3)$ |  |
| Constant | 4.012 | 3.924 | 3.778 |  |
|  | $(.349)$ | $(.379)$ | $(.381)$ |  |
| Log(wage) | -.688 | -.685 | -.637 |  |
|  | $(.111)$ | $(.114)$ | $(.115)$ |  |
| Day shift | $\ldots$ | .011 | .134 |  |
|  |  | $(.040)$ | $(.062)$ |  |
| Minimum temperature | $\ldots$ | .126 | .024 |  |
| $<30$ | $\ldots$ | $(.053)$ | $(.058)$ |  |
| Maximum temperature |  | .041 | .055 |  |
| $\geq 80$ | $\ldots$ | $(.055)$ | $(.064)$ |  |
| Rainfall | $\ldots$ | -.022 | -.054 |  |
|  |  | $(.073)$ | $(.071)$ |  |
| Snowfall | no | -.096 | -.093 |  |
|  | no | $(.036)$ | $(.035)$ |  |
| Driver effects | .063 | no | yes |  |
| Day-of-week effects |  | .098 | yes |  |
| $R^{2}$ |  | .198 |  |  |

- Farber (2005) however cannot replicate the IV specification (too few drivers on a given day)
- Key specification: Hazard model that does not suffer from division bias - Dependent variable is dummy Stop $_{i, t}=1$ if driver $i$ stops at hour $t$ :

$$
\text { Stop }_{i, t}=\Phi\left(\alpha+\beta_{Y} Y_{i, t}+\beta_{h} h_{i, t}+\Gamma X_{i, t}\right)
$$

- Control for hours worked so far $\left(h_{i, t}\right)$ and other controls $X_{i, t}$
- Does a higher earned income $Y_{i, t}$ increase probability of stopping $(\beta>0)$ ?

TABLE 5
Hazard of Stopping after Trip: Normalized Probit Estimates

| Variable | $X^{*}$ | $(1)$ | $(2)$ | $(3)$ | $(4)$ | $(5)$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Total hours | 8.0 | .013 | .037 | .011 | .010 | .010 |
| Waiting hours |  | $(.009)$ | $(.012)$ | $(.005)$ | $(.005)$ | $(.005)$ |
|  | 2.5 | .010 | -.005 | .001 | .004 | .004 |
| Break hours |  | $(.010)$ | $(.012)$ | $(.006)$ | $(.006)$ | $(.005)$ |
|  | .5 | .006 | -.015 | -.003 | -.001 | -.002 |
| Shift income $\div 100$ | 1.5 | $(.008)$ | $(.011)$ | $(.005)$ | $(.005)$ | $(.005)$ |
|  |  | .053 | .036 | .014 | .016 | .011 |
| Driver (21) |  | no | yes | yes | yes | yes |
| Day of week (7) |  | no | no | yes | yes | yes |
| Hour of day (19) | $2: 00$ p.m. | no | no | yes | yes | yes |
| Log likelihood |  | $-2,039.2$ | $-1,965.0$ | $-1,789.5$ | $-1,784.7$ | $-1,767.6$ |

Nort. - The sample includes 13,461 trips in 584 shifts for 21 drivers. Probit estimates are normalized to reflect the marginal effect at $X^{*}$ of $X$ on the probability of stopping. The normalized probit estimate is $\beta \cdot \phi\left(X^{*} \beta\right)$, where $\phi(\cdot)$ is the standard normal density. The values of $X^{*}$ chosen for the fixed effects are equally weighted for each day of the week and for each driver. The hours from 5:00 a.m. to 10:00 a.m. have a common fixed effect. The evaluation point is after 5.5 driving hours, 2.5 waiting hours, and 0.5 break hour in a dry hour on a day with moderate temperatures in midtown Manhattan at $2: 00 \mathrm{p} . \mathrm{m}$. Robust standard errors accounting for clustering by shift are reported in parentheses.

- Positive, but not significant effect of $Y_{i, t}$ on probability of stopping:
- 10 percent increase in $Y(\$ 15)->1.6$ percent increase in stopping prob. (. 225 pctg. pts. increase in stopping prob. out of average 14 pctg. pts.) $->.16$ elasticity
- Cannot reject large effect: 10 pct. increase in $Y$ increase stopping prob. by 6 percent
- Qualitatively consistent with income targeting
- Also notice:
- Failure to reject standard model is not the same as rejecting alternative model (reference dependence)
- Alternative model is not spelled out
- Final step in Farber (2005): Re-analysis of Camerer et al. (1997) data with hazard model
- Use only TRIP data (small part of sample)
- No significant evidence of effect of past income $Y$
- However: Cannot reject large positive effect

TABLE 7
Driver-Specific Hazard of Stopping after Trip: Normalized Probit Estimates

|  | DRIVER |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |

- Farber (2005) cannot address the Econometric Issue 2: Is it Supply or Demand that Varies
- Fehr and Goette (AER 2007). Experiments on Bike Messengers
- Use explicit randomization to deal with Econometric Issues 1 and 2
- Combination of:
- Experiment 1. Field Experiment shifting wage and
- Experiment 2. Lab Experiment (relate to evidence on loss aversion)...
- ... on the same subjects
- Slides courtesy of Lorenz Goette

## The Experimental Setup in this Study

## Bicycle Messengers in Zurich, Switzerland

- Data: Delivery records of Veloblitz and Flash Delivery Services, 1999-2000.
- Contains large number of details on every package delivered.
$>$ Observe hours (shifts) and effort (revenues per shift).
- Work at the messenger service
- Messengers are paid a commission rate $w$ of their revenues $r_{i t}\left(w=\right.$,wage"). Earnings $w r_{i t}$
- Messengers can freely choose the number of shifts and whether they want to do a delivery, when offered by the dispatcher.
$>$ suitable setting to test for intertemporal substitution.
- Highly volatile earnings
- Demand varies strongly between days
$>$ Familiar with changes in intertemporal incentives.

## Experiment 1

## - The Temporary Wage Increase

- Messengers were randomly assigned to one of two treatment groups, A or B.
- $N=22$ messengers in each group
- Commission rate $w$ was increased by 25 percent during four weeks
- Group A: September 2000 (Control Group: B)
- Group B: November 2000 (Control Group: A)

## - Intertemporal Substitution

- Wage increase has no (or tiny) income effect.
- Prediction with time-separable prefernces, $t=$ a day:
$>$ Work more shifts
$>$ Work harder to obtain higher revenues
- Comparison between TG and CG during the experiment.
- Comparison of TG over time confuses two effects.

## Results for Hours

- Treatment group works 12 shifts, Control Group works 9 shifts during the four weeks.
- Treatment Group works significantly more shifts (X2(1) $=4.57, p<0.05$ )
- Implied Elasticity: 0.8

Figure 6: The Working Hazard during the Experiment

## Results for Effort: Revenues per shift

- Treatment Group has lower revenues than Control Group: - 6 percent. ( $t=2.338, p<0.05$ )
- Implied negative Elasticity: -0.25

> The Distribution of Revenues during the Field Experiment

- Distributions are significantly different (KS test; $p<0.05$ );

## Results for Effort, cont.

- Important caveat
- Do lower revenues relative to control group reflect lower effort or something else?
- Potential Problem: Selectivity
- Example: Experiment induces TG to work on bad days.
- More generally: Experiment induces TG to work on days with unfavorable states
$>$ If unfavorable states raise marginal disutility of work, TG may have lower revenues during field experiment than CG .
- Correction for Selectivity
- Observables that affect marginal disutility of work. Conditioning on experience profile, messenger fixed effects, daily fixed effects, dummies for previous work leave result unchanged.
- Unobservables that affect marginal disutility of work?
- Implies that reduction in revenues only stems from sign-up shifts in addition to fixed shifts.
$>$ Significantly lower revenues on fixed shifts, not even different from sign-up shifts.

## Corrections for Selectivity

- Comparison TG vs. CG without controls
- Revenues 6 \% lower (s.e.: 2.5\%)
- Controls for daily fixed effects, experience profile, workload during week, gender
- Revenues are 7.3 \% lower (s.e.: $2 \%$ )
-     + messenger fixed effects
- Revenues are 5.8 \% lower (s.e.: 2\%)
- Distinguishing between fixed and sign-up shifts
- Revenues are 6.8 percent lower on fixed shifts (s.e.: 2 \%)
- Revenues are 9.4 percent lower on sign-up shifts (s.e.: 5 \%)
$>$ Conclusion: Messengers put in less effort
- Not due to selectivity.

## Measuring Loss Aversion

- A potential explanation for the results
- Messengers have a daily income target in mind
- They are loss averse around it
- Wage increase makes it easier to reach income target
$>$ That's why they put in less effort per shift
- Experiment 2: Measuring Loss Aversion
- Lottery A: Win CHF 8, lose CHF 5 with probability 0.5 .
- $46 \%$ accept the lottery
- Lottery C: Win CHF 5, lose zero with probability 0.5; or take CHF 2 for sure
- $72 \%$ accept the lottery
- Large Literature: Rejection is related to loss aversion.
- Exploit individual differences in Loss Aversion
- Behavior in lotteries used as proxy for loss aversion.
> Does the proxy predict reduction in effort during experimental wage increase?

## Measuring Loss Aversion

- Does measure of Loss Aversion predict reduction in effort?
- Strongly loss averse messengers reduce effort substantially: Revenues are 11 \% lower (s.e.: 3 \%)
- Weakly loss averse messenger do not reduce effort noticeably: Revenues are 4 \% lower (s.e. $8 \%$ ).
- No difference in the number of shifts worked.
$>$ Strongly loss averse messengers put in less
- Supports model with daily income target

## > Others kept working at normal pace, consistent with standard economic model

- Shows that not everybody is prone to this judgment bias (but many are)

## Concluding Remarks

- Our evidence does not show that intertemporal substitution in unimportant.
- Messenger work more shifts during Experiment 1
- But they also put in less effort during each shift.
- Consistent with two competing explanantions
- Preferences to spread out workload
$>$ But fails to explain results in Experiment 2
- Daily income target and Loss Aversion
$>$ Consistent with Experiment 1 and Experiment 2
> Measure of Loss Aversion from Experiment 2 predicts reduction in effort in Experiment 1
> Weakly loss averse subjects behave consistently with simplest standard economic model.
$>$ Consistent with results from many other studies.
- Other work:
- Farber (AER 2008) goes beyond Farber (JPE, 2005) and attempts to estimate model of labor supply with loss-aversion
- Estimate loss-aversion $\delta$
- Estimate (stochastic) reference point $T$
- Same data as Farber (2005)
- Results:
- significant loss aversion $\delta$
- however, large variation in $T$ mitigates effect of loss-aversion

## - Crawford and Meng (AER 2011)

- Re-estimates the Farber paper allowing for two dimensions of reference dependence:
- Hours (loss if work more hours than $\bar{h}$ )
- Income (loss if earn less than $\bar{Y}$ )
- Re-estimates Farber (2005) data for:
- Wage above average (income likely to bind)
- Wages below average (hours likely to bind)
- Perhaps, reconciling Camerer et al. (1997) and Farber (2005)
$-w>w^{e}$ : hours binding $->$ hours explain stopping
$-w<w^{e}$ : income binding $->$ income explains stopping

Table 1: Probability of Stopping: Probit Model with Linear Effect

| Variable | (1) |  |  | (2) |  |  | (3) |  |  |

## 2 Reference Dependence: Disposition Effect

- Odean (JF, 1998)Do investors sell winning stocks more than losing stocks?
- Individual trade data from Discount brokerage house (1987-1993)
- Rare data set $->$ Most financial data sets carry only aggregate information
- Share of realized gains:

$$
P G R=\frac{\text { Realized Gains }}{\text { Realized Gains+Paper Gains }}
$$

- Share of realized losses:

$$
P L R=\frac{\text { Realized Losses }}{\text { Realized Losses+Paper Losses }}
$$

- These measures control for the availability of shares at a gain or at a loss
- Tax advantage to sell losers
- Can post a deduction to capital gains taxation
- Stronger incentives in December, can post for current tax year
- Prospect theory intuition:
- Reference point: price of purchase
- Convexity over losses —> gamble, hold on stock
- Concavity over gains —> risk aversion, sell stock

- Construction of measure:
- Observations are counted on all days in which a sale or purchase occurs
- On those days the paper gains and losses are counted
- Reference point is average purchase price:
- Example: $P G R=\frac{13,883}{13,883+79,658}=0.148$

Table I

## PGR and PLR for the Entire Data Set

This table compares the aggregate Proportion of Gains Realized (PGR) to the aggregate Proportion of Losses Realized (PLR), where PGR is the number of realized gains divided by the number of realized gains plus the number of paper (unrealized) gains, and PLR is the number of realized losses divided by the number of realized losses plus the number of paper (unrealized) losses. Realized gains, paper gains, losses, and paper losses are aggregated over time (19871993) and across all accounts in the data set. PGR and PLR are reported for the entire year, for December only, and for January through November. For the entire year there are 13,883 realized gains, 79,658 paper gains, 11,930 realized losses, and 110,348 paper losses. For December there are 866 realized gains, 7,131 paper gains, 1,555 realized losses, and 10,604 paper losses. The $t$-statistics test the null hypotheses that the differences in proportions are equal to zero assuming that all realized gains, paper gains, realized losses, and paper losses result from independent decisions.

|  | Entire Year | December | Jan.-Nov. |
| :--- | :---: | :---: | ---: |
| PLR | 0.098 | 0.128 | 0.094 |
| PGR | 0.148 | 0.108 | 0.152 |
| Difference in proportions | -0.050 | 0.020 | -0.058 |
| $t$-statistic | -35 | 4.3 | -38 |

- Strong support for disposition effect
- Effect monotonically decreasing across the year

- Tax reasons are also at play
- Robustness: Across years and across types of investors

|  |  |  | Frequent <br> Traders | Infrequent <br> Traders |
| :--- | :---: | :---: | :---: | ---: |
| Entire year PLR | $1987-1990$ | $1991-1993$ | 0.072 | 0.079 |
| Entire year PGR | 0.126 | 0.115 | 0.119 | 0.296 |
| Difference in proportions | -0.075 | -0.043 | -0.040 | 0.452 |
| $t$-statistic | -30 | -25 | -29 | -0.156 |
|  |  |  | -22 |  |

- Alternative Explanation 1: Rebalancing -> Sell winners that appreciated
- Remove partial sales

|  | Entire Year | December |
| :--- | :---: | :---: |
| PLR | 0.155 | 0.197 |
| PGR | 0.233 | 0.162 |
| Difference in proportions | -0.078 | 0.035 |
| $t$-statistic | -32 | 4.6 |

- Alternative Explanation 2: Ex-Post Return -> Losers outperform winners ex post
- Table VI: Winners sold outperform losers that could have been sold

|  | Performance over <br> Next 84 <br> Trading Days | Performance over <br> Next 252 <br> Trading Days | Performance over <br> Next 504 <br> Trading Days |
| :--- | :---: | :---: | :---: |
| Average excess return on <br> winning stocks sold | 0.0047 | 0.0235 | 0.0645 |
| Average excess return on <br> paper losses | -0.0056 | -0.0106 | 0.0287 |
| Difference in excess returns <br> $(p$-values $)$ | 0.0103 | 0.0341 | 0.0358 |

- Alternative Explanation 3: Transaction costs $->$ Losers more costly to trade (lower prices)
- Compute equivalent of $P G R$ and $P L R$ for additional purchases of stock
- This story implies $P G P>P L P$
- Prospect Theory implies $P G P<P L P$ (invest in losses)
- Evidence:

$$
\begin{aligned}
P G P & =\frac{\text { Gains Purchased }}{\text { Gains Purchased }+ \text { Paper Gains }}=.094 \\
& <P L P=\frac{\text { Losses Purchased }}{\text { Losses Purchased }+ \text { Paper Losses }}=.135 .
\end{aligned}
$$

- Alternative Explanation 4: Belief in Mean Reversion -> Believe that losers outperform winners
- Behavioral explanation: Losers do not outperform winners
- Predicts that people will buy new losers $->$ Not true
- How big of a cost? Assume $\$ 1000$ winner and $\$ 1000$ loser
- Winner compared to loser has about \$850 in capital gain $->\$ 130$ in taxes at $15 \%$ marginal tax rate
- Cost 1: Delaying by one year the $\$ 130$ tax ded. $->\$ 10$
- Cost 2: Winners overperform by about 3\% per year -> \$34
- Ivkovich, Poterba, and Weissbenner (AER 2005)
- Compare taxable accounts and tax-deferred plans (IRAs)
- Disposition effect should be stronger for tax-deferred plans
- Methodology:
- Hazard regressions of probability of buying and selling monthly, instead of $P G R$ and $P L R$
- Avoid selection involved in computing PGR/PLR only when sale
- For each month $t$, estimate linear probability model:

$$
S E L L_{i, t}=\alpha_{t}+\beta_{1, t} I(\text { Gain })_{i, t-1}+\beta_{2, t} I(\text { Loss })_{i, t-1}+\varepsilon_{i, t}
$$

- $\alpha_{t}$ is baseline hazard at month $t$
- $\beta s$ always consistent with disposition effect, except in December

Notes: Sample is January purchases of stock 1991-96 in taxable accounts. The hazard rate for stock purchases unconditional on the stock's price performance, as well as conditional on whether the stock has an accrued capital gain or loss entering the month, is displayed.

Notes: Sample is January purchases of stock of at least $\$ 10,000$ from 1991-96. The hazard rate for stock purchases conditional on whether the stock has an accrued capital gain or loss entering the month is displayed for taxable and tax-deferred accounts.

Notes: Sample is January purchases of stock 1991-96. If $h(t)$ denotes the hazard rate in month $t$, the probability that the stock is sold by the end of month $t$ is $\left[1-\left(\Pi_{s=1, t}(1-h(s))\right)\right]$. Figure 4 displays cumulative probability of sale in a taxable account less that in a tax-deferred account for each month.

-     - Different hazards between taxable and tax-deferred accounts ->Taxes
- Disposition Effect very solid finding. Explanation?
- Barberis and Xiong (JF 2009). Model asset prices with full prospect theory (loss aversion+concavity+convexity), except for prob. weighting
- Under what conditions prospect theory generates disposition effect?
- Setup:
- Individuals can invest in risky asset or riskless asset with return $R_{f}$
- Can trade in $t=0,1, \ldots, T$ periods
- Utility is evaluated only at end point, after $T$ periods
- Reference point is initial wealth $W_{0}$
- utility is $v\left(W_{T}-W_{0} R_{f}\right)$

## - Calibrated model: Prospect theory may not generate disposition effect!

Table 2: For a given $(\mu, T)$ pair, we construct an artificial dataset of how 10,000 investors with prospect theory preferences, each of whom owns $N_{S}$ stocks, each of which has an annual gross expected return $\mu$, would trade those stocks over $T$ periods. For each $(\mu, T)$ pair, we use the artifical dataset to compute PGR and PLR, where PGR is the proportion of gains realized by all investors over the entire trading period, and PLR is the proportion of losses realized. The table reports "PGR/PLR" for each $(\mu, T)$ pair. Boldface type identifies cases where the disposition effect fails (PGR $<$ PLR). A hyphen indicates that the expected return is so low that the investor does not buy any stock at all.

| $\mu$ | $T=2$ | $T=4$ | $T=6$ | $T=12$ |
| :---: | :---: | :---: | :---: | :---: |
| 1.03 | - | - | - | .55/.50 |
| 1.04 | - | - | . $54 / .52$ | . $54 / .52$ |
| 1.05 | - | - | . $54 / .52$ | . $59 / .45$ |
| 1.06 | - | . $70 / .25$ | .54/.52 | . $58 / .47$ |
| 1.07 | - | . $70 / .25$ | . $54 / .52$ | . $57 / .49$ |
| 1.08 | - | . $70 / .25$ | . $48 / .58$ | . $47 / .60$ |
| 1.09 | - | .43/.70 | . $48 / .58$ | . $46 / .61$ |
| 1.10 | 0.0/1.0 | .43/.70 | . $48 / .58$ | . $36 / .69$ |
| 1.11 | 0.0/1.0 | .43/.70 | . $49 / .58$ | . $37 / .68$ |
| 1.12 | 0.0/1.0 | .28/.77 | .23/81 | . $40 / .66$ |
| 1.13 | 0.0/1.0 | .28/.77 | .24/83 | .25/.78 |

- Intuition:
- Previous analysis of reference-dependence and disposition effect focused on concavity and convexity of utility function
- Neglect of kink at reference point (loss aversion)
- Loss aversion induces high risk-aversion around the kink -> Two effects

1. Agents purchase risky stock only if it has high expected return
2. Agents sell if price of stock is around reference point

- Now, assume that returns are high enough and one invests:
* on gain side, likely to be far from reference point $->$ do not sell, despite (moderate) concavity
* on loss side, likely to be close to reference point $->$ may lead to more sales (due to local risk aversion), despite (moderate) convexity

- Some novel predictions of this model:
- Stocks near buying price are more likely to be sold, all else constant
- Disposition effect should hold when away from ref. point
- Meng (2010) elaborates on this point
- Model of two-period portfolio holding
- Loss Aversion with respect to (potentially stochastic) reference point
- Derives optimal value of holding of risk asset $x$ as function of past returns

- Empirical test: When the return is near the purchase price we should see
- More selling
- Less buying
$-\longrightarrow$ The selling hazard should be an inverse $V$-shaped function of price
$->$ The buying hazard should be a $V$-shaped function of price
- Ben-David and Hirshleifer (RFS 2012) plot the hazards above, that is,
- $P($ Sell at $t \mid h o l d i n g ~ a t ~ t)$
- $P($ Buy more at $t \mid h o l d i n g$ at $t)$

| Probability of Selling Shares | Probability of Buying Additional Shares |
| :---: | :---: |
| Day 1 | Day 1 |
|  |  |
| Day 5 | Day 5 |
|  |  |
| Day 20 | Day 20 |
|  |  |

- Results
- Strikingly, probability of selling minimal for $P_{t}=P_{0}$
- Rejection of prospect theory model with purchase price as reference point.
- Could reference point be expected return (that is, $\left.P_{0} *(1+r)\right)$ ?
- BUT No visible inverse V-shaped pattern for positive return
- Back to the drawing board
- Barberis-Xiong assumes that utility is evaluated every $T$ period for all stocks
- Alternative assumption: Investors evaluate utility only when selling
- Realization utility: Barberis and Xiong (JFE 2012)
- Individuals get utility only they liquidate a portfolio
- Assume (piece-wise) linear realization utility
- Loss from selling a loser > Gain of selling winner
- Sell winners when go above a certain threshold value
- Never sell losers, hoping in option value
- Explains disposition effect $->$ But too extreme
- Follow-up: Ingersoll-Jin (RFS 2013)
- Realization Utilty model
- Assume value function as in prospect theory: concave over loss, convex over gains
- Convexity of gains $->$ Sell losses if big enough so get to reset the clock
- On gains -> Sell gains past a threshold
- Table 1: Calibration with loss aversion $\lambda=2$ for varying concavity over gains $\left(\alpha_{G}\right)$ and over losses $\left(\alpha_{L}\right)$

Table 1
Summary statistics for reference-dependent realization utility model with scaled Tversky-Kahneman utility

The table reports $\Theta-1, \theta-1$ : percentages above and below the reference level for realized gains and losses, $Q_{G}$ : fraction of episodes that end in realized gains, $\varphi_{G}$ : fraction of stocks with unrealized paper gains, $\mathbb{E}[\tau]$ : average holding period in trading days ( 250 per year), $P G R, P L R$ : proportions of gains and losses realized, and $\mathcal{O} \equiv P G R / P L R$ : Odean's measure. Asset parameters are $\mu=9 \%$ and $\sigma=30 \%$. The accounts' sizes are fixed with $\bar{n}+\sigma_{n}^{2} / \bar{n}=8.0$. Utility parameters are $\lambda=2$ and $\delta=5 \%$ (except $\delta=8 \%$ for $\alpha_{G}=0.88$ and $\delta=10 \%$ for $\alpha_{G}=1$ to avoid a transversality violation). Transaction costs are $k_{s}=k_{p}=1 \%$, and the investor accounts for both costs in his

- Can also explain V-shape in selling

- But what about V-shape in buying?
- Ongoing debate in the literature

## - Karlsson, Loewenstein, and Seppi (JRU 2009): Ostrich Effect

- Investors do not want to evaluate their investments at a loss
- Stock market down -> Fewer logins into investment account

Figure 4b: Changes in the SAX and ratio of fund look-ups to logins to personal banking page by investors at a large Swedish bank
The sample period is June 30, 2003 through October 7, 2003.

## 3 Reference Dependence: Equity Premium

- Disposition Effect is about cross-sectional returns and trading behavior -> Compare winners to losers
- Now consider reference dependence and market-wide returns
- Benartzi and Thaler (1995)
- Equity premium (Mehra and Prescott, 1985)
- Stocks not so risky
- Do not covary much with GDP growth
- BUT equity premium $3.9 \%$ over bond returns (US, 1871-1993)
- Need very high risk aversion: $R R A \geq 20$
- Benartzi and Thaler: Loss aversion + narrow framing solve puzzle
- Loss aversion from (nominal) losses—> Deter from stocks
- Narrow framing: Evaluate returns from stocks every $n$ months
- More frequent evaluation->Losses more likely $->$ Fewer stock holdings
- Calibrate model with $\lambda$ (loss aversion) 2.25 and full prospect theory specification $->$ Horizon $n$ at which investors are indifferent between stocks and bonds

- If evaluate every year, indifferent between stocks and bonds
- (Similar results with piecewise linear utility)
- Alternative way to see results: Equity premium implied as function on $n$

- Barberis, Huang, and Santos (2001)
- Piecewise linear utility, $\lambda=2.25$
- Narrow framing at aggregate stock level
- Range of implications for asset pricing
- Barberis and Huang (2001)
- Narrowly frame at individual stock level (or mutual fund)

## 4 Reference Dependence: Domestic Violence

- Consider a man in conflicted relationship with the spouse
- What is the effect of an event such as the local football team losing or winning a game?
- With probability $h$ the man loses control and becomes violent
- Assume $h=h(u)$ with $h^{\prime}<0$ and $u$ the underlying utility
- Denote by $p$ the ex-ante expectation that the team wins
- Denote by $u(W)$ and $u(L)$ the consumption utility of a loss
- Using a Koszegi-Rabin specification, then ex-post the utility from a win
is

$$
\begin{aligned}
U(W \mid p)= & u(W) \text { [consumption utility] } \\
& +p[0]+(1-p) \eta[u(W)-u(L)] \text { [gain-loss utility] }
\end{aligned}
$$

- Similarly, the utility from a loss is

$$
U(L \mid p)=u(L)+(1-p)[0]-\lambda p \eta[u(W)-u(L)]
$$

- Implication:

$$
\partial U(L \mid p) / \partial p=-\lambda \eta[u(W)-u(L)]<0
$$

- The more a win is expected, the more a loss is painful $->$ the more likely it is to trigger violence
- The (positive) effect of a gain is higher the more unexpected (lower $p$ )
- Card and Dahl (QJE 2011) test these predictions using a data set of:
- Domestic violence (NIBRS)
- Football matches by State
- Expected win probability from Las Vegas predicted point spread
- Separate matches into
- Predicted win (+3 points of spread)
- Predicted close
- Predicted loss (-3 points)

Table 4. Emotional Shocks from Football Games and Male-on-Female Intimate Partner Violence Occurring at Home, Poisson Regressions.

|  | Intimate Partner Violence, Male on Female, at Home Baseline Model |  |  |  |  |

| Observations | 77,520 | 77,520 | 77,520 | 71,798 | 71,798 |

- Findings:

1. Unexpected loss increase domestic violence
2. No effect of expected loss
3. No effect of unexpected win, if anything increases violence

- Findings 1-2 consistent with ref. dep. and 3 partially consistent (given that violence is a function is very negative utility)
- Other findings:
- Effect is larger for more important games
- Effect disappears within a few hours of game end -> Emotions are transient
- No effect on violence of females on males

## 5 Reference Dependence: Insurance

- Much of the laboratory evidence on prospect theory is on risk taking
- Field evidence considered so far (mostly) does not involve risk:
- Trading behavior - Endowment Effect
- House Sale
- Merger Offer
- Field evidence on risk taking?
- Sydnor (2010) on deductible choice in the life insurance industry
- Uses Menu Choice as identification strategy as in DellaVigna and Malmendier (2006)
- Slides courtesy of Justin Sydnor

## Dataset

- 50,000 Homeowners-Insurance Policies
- 12\% were new customers
- Single western state
- One recent year (post 2000)
- Observe
- Policy characteristics including deductible
- 1000, 500, 250, 100
- Full available deductible-premium menu
- Claims filed and payouts by company

## Features of Contracts

- Standard homeowners-insurance policies (no renters, condominiums)
- Contracts differ only by deductible
- Deductible is per claim
- No experience rating
- Though underwriting practices not clear
- Sold through agents
- Paid commission
- No "default" deductible
- Regulated state

## Summary Statistics

Chosen Deductible

| Variable | Full |  | 500 | 250 | 100 |
| :---: | :---: | :---: | :---: | :---: | :---: |

## Potential Savings with 1000 Ded

## Claim rate?

## Value of lower

 deductible? Additional premium?Potential savings?

Average forgone expected savings for all low-deductible customers: \$99.88

[^0]
## Back of the Envelope

- BOE 1: Buy house at 30, retire at 65, $3 \%$ interest rate $\Rightarrow \$ 6,300$ expected
- With 5\% Poisson claim rate, only 0.06\% chance of losing money
- BOE 2: (Very partial equilibrium) 80\% of 60 million homeowners could expect to save $\$ 100$ a year with "high" deductibles $\Rightarrow \$ 4.8$ billion per year

## Consumer Inertia?

Percent of Customers Holding each Deductible Level

## Look Only at New Customers

|  |  | Increase in out-of- <br> pocket payments <br> per claim with a <br> Number of claims <br> per policy | Incent-of- <br> pocket payments <br> per policy with a <br> \$1000 deductible | Reduction in <br> yearly premium <br> per policy with | Savings per policy <br> with $\$ 1000$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Chosen Deductible | 0.037 | 475.05 | 17.16 | 94.53 | 77.37 |
| $\$ 500$ | $(.0035)$ | $(7.96)$ | $(1.66)$ | $(0.55)$ | $(1.74)$ |
| $\mathrm{N}=3,424(54.6 \%)$ | 0.057 | 641.20 | 35.68 | 154.90 | 119.21 |
| $\$ 250$ | $(.0127)$ | $(43.78)$ | $(8.05)$ | $(2.73)$ | $(8.43)$ |

Average forgone expected savings for all low-deductible customers: \$81.42

## Risk Aversion?

- Simple Standard Model
- Expected utility of wealth maximization
- Free borrowing and savings
- Rational expectations
- Static, single-period insurance decision
- No other variation in lifetime wealth

## Model of Deductible Choice

- Choice between ( $\mathrm{P}_{\mathrm{L}}, \mathrm{D}_{\mathrm{L}}$ ) and ( $\mathrm{P}_{\mathrm{H}}, \mathrm{D}_{\mathrm{H}}$ )
- $\pi=$ probability of loss
- Simple case: only one loss
- EU of contract:
- $\mathrm{U}(\mathrm{P}, \mathrm{D}, \pi)=\pi \mathrm{u}(\mathrm{w}-\mathrm{P}-\mathrm{D})+(1-\pi) \mathrm{u}(\mathrm{w}-\mathrm{P})$

## Bounding Risk Aversion

Assume CRRA form for $u$ :

$$
u(x)=\frac{x^{(1-\rho)}}{(1-\rho)} \quad \text { for } \rho \neq 1, \quad \text { and } \quad u(x)=\ln (x) \text { for } \rho=1
$$

Indifferent between contracts iff:

$$
\pi \frac{\left(w-P_{L}-D_{L}\right)^{(1-\rho)}}{(1-\rho)}+(1-\pi) \frac{\left(w-P_{L}\right)^{(1-\rho)}}{(1-\rho)}=\pi \frac{\left(w-P_{H}-D_{H}\right)^{(1-\rho)}}{(1-\rho)}+(1-\pi) \frac{\left(w-P_{H}\right)^{(1-\rho)}}{(1-\rho)}
$$

## Getting the bounds

- Search algorithm at individual level
- New customers
- Claim rates: Poisson regressions
- Cap at 5 possible claims for the year
- Lifetime wealth:
- Conservative: $\$ 1$ million (40 years at $\$ 25 \mathrm{k}$ )
- More conservative: Insured Home Value

## CRRA Bounds

Measure of Lifetime Wealth (W): (Insured Home Value)
Chosen Deductible
\$1,000
$\mathrm{N}=2,474$ (39.5\%)
\$500
$N=3,424$ (54.6\%)
\$250
166,007 780
2,467
$\mathrm{N}=367$ (5.9\%)
\{57,613\} (20.380)
(59.130)

## Interpreting Magnitude

- 50-50 gamble:

Lose \$1,000/ Gain \$10 million

- 99.8\% of low-ded customers would reject
- Rabin (2000), Rabin \& Thaler (2001)
- Labor-supply calibrations, consumptionsavings behavior $\Rightarrow \rho<10$
. Gourinchas and Parker (2002) -- 0.5 to 1.4
- Chetty (2005) -- < 2

## Wrong level of wealth?

- Lifetime wealth inappropriate if borrowing constraints.
- \$94 for \$500 insurance, $4 \%$ claim rate
- $\mathrm{W}=\$ 1$ million $\Rightarrow \rho=2,013$
- $\mathrm{W}=\$ 100 \mathrm{~K} \quad \Rightarrow \rho=199$
- $W=\$ 25 k \quad \Rightarrow \rho=48$

## Prospect Theory

- Kahneman \& Tversky (1979, 1992)
- Reference dependence
- Not final wealth states
- Value function
- Loss Aversion
- Concave over gains, convex over losses
- Non-linear probability weighting

## Model of Deductible Choice

- Choice between ( $\mathrm{P}_{\mathrm{L}}, \mathrm{D}_{\mathrm{L}}$ ) and ( $\mathrm{P}_{\mathrm{H}}, \mathrm{D}_{\mathrm{H}}$ )
- $\pi=$ probability of loss
- EU of contract:
- $\mathrm{U}(\mathrm{P}, \mathrm{D}, \pi)=\pi \mathrm{u}(\mathrm{w}-\mathrm{P}-\mathrm{D})+(1-\pi) \mathrm{u}(\mathrm{w}-\mathrm{P})$
- PT value:
- $\mathrm{V}(\mathrm{P}, \mathrm{D}, \pi)=\mathrm{v}(-\mathrm{P})+\mathrm{w}(\pi) \mathrm{v}(-\mathrm{D})$
- Prefer ( $\mathrm{P}_{\mathrm{L}}, \mathrm{D}_{\mathrm{L}}$ ) to ( $\mathrm{P}_{\mathrm{H}}, \mathrm{D}_{\mathrm{H}}$ )
- $v\left(-P_{L}\right)-v\left(-P_{H}\right)<w(\pi)\left[v\left(-D_{H}\right)-v\left(-D_{L}\right)\right]$

## No loss aversion in buying

- Novemsky and Kahneman (2005)
(Also Kahneman, Knetsch \& Thaler (1991))
- Endowment effect experiments
- Coefficient of loss aversion = 1 for "transaction money"
- Köszegi and Rabin (forthcoming QJ E, 2005)
- Expected payments
- Marginal value of deductible payment > premium payment (2 times)

## So we have:

- Prefer ( $\mathrm{P}_{\mathrm{L}}, \mathrm{D}_{\mathrm{L}}$ ) to ( $\mathrm{P}_{\mathrm{H}}, \mathrm{D}_{\mathrm{H}}$ ):

$$
v\left(-P_{L}\right)-v\left(-P_{H}\right)<w(\pi)\left[v\left(-D_{H}\right)-v\left(-D_{L}\right)\right]
$$

- Which leads to:

$$
P_{L}^{\beta}-P_{H}^{\beta}<w(\pi) \lambda\left[D_{H}^{\beta}-D_{L}^{\beta}\right]
$$

- Linear value function:

$$
\begin{aligned}
W T P=\Delta P & =\underbrace{w(\pi) \lambda \Delta D} \\
& =4 \text { to } 6 \text { times } \mathrm{EV}
\end{aligned}
$$

## Choices: Observed vs. Model

|  | Predicted Deductible Choice from Prospect Theory NLIB Specification:$\lambda=2.25, \gamma=0.69, \beta=0.88$ |  |  |  | Predicted Deductible Choice from EU(W) CRRA Utility:$\rho=10, \mathrm{~W}=\text { Insured Home Value }$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Chosen Deductible | 1000 | 500 | 250 | 100 | 1000 | 500 | 250 | 100 |
| $\begin{aligned} & \$ 1,000 \\ & \quad N=2,474(39.5 \%) \end{aligned}$ | 87.39\% | 11.88\% | 0.73\% | 0.00\% | 100.00\% | 0.00\% | 0.00\% | 0.00\% |
| $\begin{aligned} & \$ 500 \\ & \quad N=3,424(54.6 \%) \end{aligned}$ | 18.78\% | 59.43\% | 21.79\% | 0.00\% | 100.00\% | 0.00\% | 0.00\% | 0.00\% |
| $\begin{aligned} & \$ 250 \\ & \quad N=367(5.9 \%) \end{aligned}$ | 3.00\% | 44.41\% | 52.59\% | 0.00\% | 100.00\% | 0.00\% | 0.00\% | 0.00\% |
| $\begin{aligned} & \$ 100 \\ & \quad N=3(0.1 \%) \\ & \hline \end{aligned}$ | 33.33\% | 66.67\% | 0.00\% | 0.00\% | 100.00\% | 0.00\% | 0.00\% | 0.00\% |

## Alternative Explanations

- Misestimated probabilities
- $\approx 20 \%$ for single-digit CRRA
- Older (age) new customers just as likely
- Liquidity constraints
- Sales agent effects
- Hard sell?
- Not giving menu? (\$500?, data patterns)
- Misleading about claim rates?
- Menu effects
- Barseghyan, Molinari, O'Donoghue, and Teitelbaum (AER 2012)
- Micro data for same person on 4,170 households for 2005 or 2006 on * home insurance
* auto collision insurance
* auto comprehensive insurance
- Estimate a model of reference-dependent preferences with Koszegi-Rabin reference points
- Separate role of loss aversion, curvature of value function, and probability weighting
- Key to identification: variation in probability of claim:
-     * home insurance $->0.084$
* auto collision insurance $->0.069$
* auto comprehensive insurance $->0.021$

Figure 1: Empirical Density Functions for Predicted Claim Probabilities

- This allows for better identification of probability weighting function
- Main result: Strong evidence from probability weighting, implausible to obtain with standard risk aversion
- Share of probability weighting function
- With probability weighting, realistic demand for low-deductible insurance
- Follow-up work: distinguish probability weighting from probability distortion

Figure 2: Eatimated $\Omega(\mu)-$ Model 1

Table 6: Economic Significance

|  | (1) | (2) | (3) | (4) | (5) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Standard risk aversion | $\mathbf{r}=\mathbf{0}$ | $\mathbf{r}=\mathbf{0 . 0 0 0 6 4}$ | $\mathbf{r}=\mathbf{0}$ | $\mathrm{r}=\mathbf{0 . 0 0 0 6 4}$ | $\mathbf{r}=\mathbf{0 . 0 1 2 9}$ |
| Probability distortions? | No | No | Yes | Yes | No |
| $\boldsymbol{\mu}$ | WTP | WTP | WTP | WTP | WTP |
| $\mathbf{0 . 0 2 0}$ | 10.00 | 14.12 | 41.73 | 57.20 | 33.76 |
| $\mathbf{0 . 0 5 0}$ | 25.00 | 34.80 | 55.60 | 75.28 | 75.49 |
| $\mathbf{0 . 0 7 5}$ | 37.50 | 51.60 | 67.30 | 90.19 | 104.86 |
| $\mathbf{0 . 1 0 0}$ | 50.00 | 68.03 | 77.95 | 103.51 | 130.76 |
| $\mathbf{0 . 1 2 5}$ | 62.50 | 84.11 | 86.41 | 113.92 | 154.00 |

Notes: WTP denotes - for a household with claim rate $\mu$, the utility function in equation (2), and the specified utility parameters-the household's maximum willingness to pay to reduce its deductible from $\$ 1000$ to $\$ 500$ when the premium for coverage with a $\$ 1000$ deductible is $\$ 200$. Columns (3) and (4) use the probability distortion estimates from Model 1a.
