

## LECTURE 9

# The Effects of Credit Contraction and Financial Crises: Balance Sheet and Cash Flow Effects

October 24, 2018

# I. OVERVIEW AND GENERAL ISSUES

# The Big Picture

- Many of our baseline models (both Keynesian and classical) assume perfect financial markets—for example, a single interest rate.
- But financial markets are not perfect!

# Changes in Financial Market Imperfections Can Affect the Economy

- The changes can be an endogenous response to the state of the economy—financial market imperfections as a propagation mechanism.
- Or the changes can occur for a given state of the economy—financial market imperfections as a source of shocks.

# Overview of the Next Several Lectures

- Today: How the state of households and firms affects their ability to get credit and their behavior (balance sheet and cash flow effects).
- Oct. 31: Disruptions to financial intermediation: Aggregate evidence on financial crises.
- Nov. 28: Disruptions to financial intermediation, continued: Microeconomic evidence.

# The Nature of Financial Market Imperfections

- In most models, they take the form of asymmetric information between borrowers and lenders creating “agency costs.”
- Example: Monitoring and screening costs.
- One implication is that there is likely to be a gap between the costs of internal and external finance.
- There is asymmetric information both between savers and financial intermediaries and between the intermediaries and borrowers.
- Financial market imperfections can affect both AD and AS.

# Today's Papers

- How the financial health of firms and households (their balance sheets and cash flows) affects their behavior.
- CH and LM: Evidence about financial market imperfections and firm behavior, and about the nature of the imperfections.
- MRS: The impact of households' balance sheets on their behavior—specifically, their response to changes in housing wealth.

## II. CALOMIRIS AND HUBBARD, “INTERNAL FINANCE AND INVESTMENT: EVIDENCE FROM THE UNDISTRIBUTED PROFITS TAX OF 1936–37”

# Issues Calomiris and Hubbard Address

- Is there a difference in cost between external and internal finance?
- Is it caused by asymmetric information or by entrenched managers?
- Does the existence of a spread cause investment to depend on cash flow?

# Calomiris and Hubbard's Natural Experiment

- Surtax on Undistributed Profits in effect in 1936 and 1937.
- Tax on retained earnings.
- Different rates depending on how much of earnings were retained.

**TABLE 1**      **Retained Earnings as a Percentage of After-Tax Profits for Corporations with Positive Income, 1931–40**

|         | Under 50 | 50–100 | 100–250 | 250–500 | 500–1,000 | 1,000–5,000 | 5,000–10,000 | 10,000–50,000 | Over 50,000 | All Classes |
|---------|----------|--------|---------|---------|-----------|-------------|--------------|---------------|-------------|-------------|
| 1931    | 57.3     | 47.8   | 39.1    | 32.1    | 26.4      | 21.5        | 13.9         | 11.1          | 3.7*        | 9.6         |
| 1932    | 39.9     | 31.5   | 31.6    | 28.8    | 26.1      | 20.8        | 12.6         | 7.6           | 8.9*        | 4.3         |
| 1933    | 64.0     | 66.5   | 61.4    | 61.3    | 56.5      | 47.1        | 39.4         | 22.2          | 2.5*        | 24.0        |
| 1934    | 53.7†    | 57.1   | 52.6    | 45.5    | 34.9      | 25.8        | 28.5         | 3.5           | 13.9        | 19.7        |
| 1935    | 56.4     | 52.0   | 48.5    | 44.5    | 34.7      | 28.2        | 20.5         | 8.0           | 19.8        | 23.0        |
| 1936    | 35.8     | 28.4   | 23.8    | 22.7    | 25.8      | 25.9        | 22.3         | 15.6          | 4.9         | 15.1        |
| 1937    | 30.4     | 29.4   | 24.1    | 22.8    | 23.2      | 22.2        | 20.7         | 16.0          | 8.3         | 15.1        |
| 1938    | 50.6     | 54.8   | 48.3    | 39.3    | 37.8      | 29.5        | 23.7         | 16.8          | 7.3         | 19.2        |
| 1939    | 62.0     | 63.1   | 55.6    | 46.1    | 44.6      | 37.8        | 33.9         | 24.2          | 18.3        | 28.8        |
| 1940    | 62.2     | 59.2   | 56.4    | 51.2    | 50.1      | 44.3        | 39.0         | 30.1          | 22.3        | 33.2        |
| Average | 51.1     | 48.1   | 44.1    | 39.4    | 36.0      | 30.3        | 25.5         | 15.5          | 8.0         | 19.2        |

SOURCE.—Butters and Lintner (1945, p. 66).

NOTE.—Asset size classes are in thousands of dollars.

\* Indicates an excess of dividends over net profits after taxes.

† This item represents nonfinancial corporations only, because of the abnormal dividends paid by financial corporations of this size in 1934.

SOURCE.—Figures are derived from U.S. Internal Revenue Service (1937).

NOTE.—Classifications are by highest surtax rate paid.

From: Calomiris and Hubbard, "Internal Finance and Investment"

# Evaluation of the Natural Experiment

- Creative and potentially very useful.
- Only tells us about relatively large firms.
- Tax paid could reflect something other than the true difference between the cost of internal and external finance.

# Data

- Firm level data for 273 firms.
- Use many sources to get data on dividends, equity, income, investment, cash flow.
- Estimate the top marginal surtax paid.
- Evaluation?
  - Impressive, hard data collection.
  - Lots of inconsistencies, dropped observations, judgment calls, etc.
  - Could there be selection bias?

## Classification Based on Top SUP Rate

- Type A: 0, 7, or 12%
- Type B: 17%
- Type C: 22 or 27%

**TABLE 4**      **Characteristics of Firms, by Surtax Margin**

|   | Type A  | Type B  | Type C | All Firms |

# Discussion

### III. LIAN AND MA, “ANATOMY OF CORPORATE BORROWING CONSTRAINTS”

# Overview

- Lian and Ma are especially interested in the nature of financial market imperfections affecting firms, and in the implications for what can cause those constraints to change.

# Background

- A large empirical literature finds evidence that cash flow has a causal effect on investment.
- A large theoretical literature is built on the assumption that the value of collateral is important to borrowing constraints.

## Aggregate Facts

- The distinction between “asset-based lending” and “cash flow-based lending.”
- “[A]sset-based lending accounts for roughly 20% of debt by value .... [C]ash flow-based lending accounts for about 80% of debt by value.”
- “[I]n the context of cash flow-based lending, a common form of borrowing constraint stipulates debt limits based on ... EBITDA (earnings before interest, tax, depreciation, and amortization).”

# Disaggregate Facts

- Cash flow-based lending is less common:
  - For firms with assets that are less specialized (airlines, utilities).
  - For firms with lower cash flow (small firms, low-profit large firms).
  - In legal environments less supportive of continuing operation of bankrupt firms (Japan).

# The Behavior of Investment and Debt

- Lian and Ma examine how investment and debt vary with cash flow and/or debt for various types of firms.
- Motivation is similar to Fazzari-Hubbard-Petersen: Comparisons of how outcomes vary with cash flow across different types of firms are especially informative.
- Lian and Ma argue that how outcomes vary with EBITDA controlling for cash flow is also especially informative.

# Framework

- Notation:  $I$  investment,  $b$  borrowing,  $CF$  cash flow,  $\pi$  EBITDA,  $A$  value of assets,  $C$  marginal cost of borrowing.
- $b = \max\{I - CF, 0\}$ .
- FHP view:  $C = C(b)$ ,  $C'(b) > 0$ .
- Collateral view:  $C = C(b, A)$ ,  $C_b > 0$ ,  $C_A < 0$ ,  $C_{bA} < 0$ .
- Lian-Ma view:  $C = C(b, \pi)$ ,  $C_b > 0$ ,  $C_\pi < 0$ ,  $C_{b\pi} < 0$ .

From: Lian and Ma, "Anatomy of Corporate Borrowing Constraints"

# Conclusions

- In most developed economies, for the firms that do most of investment, borrowing limits are determined by cash flow, not collateral.
- Implications:
  - A different interpretation of the cash flow–investment link.
  - Collateral values (and propagation of shocks through collateral values) may be less important than previously thought.
- These findings may have implications for policy.

## IV. MIAN, RAO, AND SUFI, “HOUSEHOLD BALANCE SHEETS, CONSUMPTION, AND THE ECONOMIC SLUMP”

# Subject

- Impact of the fall in household wealth in 2006–2009 on consumption.
- Especially: Heterogeneity in MPCs out of housing wealth (from either credit constraints or a consumption function that is concave in wealth).
  - Such heterogeneity would likely be due largely to financial market imperfections and borrowing constraints.
  - So, closely related to “asset-based lending” and collateral effects.
- Focus is on regional variation.

## Taking a Step Back: Some Bigger Picture Questions about the Run-Up in House Prices and the Great Recession

- Was the explosion of mortgage debt driven fundamentally by overoptimism about house prices or by a shift in credit supply?
- To what extent was the expansion of mortgage availability concentrated in “low quality” borrowers?
- How important was the health of the banking system to the Great Recession and (especially) to the slow recovery?

# Organizing Framework

$$\Delta \log C_t^i = \alpha_t + \beta * \Delta \log X_t^i + \varepsilon_t^i.$$

( $X_t^i$  is the wealth of household  $i$ .)

$$\begin{aligned} \Delta C_t^i = & \alpha_t + \beta_1 * \Delta NW_t^i \\ & + \beta_2 * NW_{t-1}^i + \beta_3 * \Delta NW_t^i * NW_{t-1}^i + \varepsilon_t^i. \end{aligned}$$

( $NW_t^i$  is the net worth of household  $i$ .)

# Data and Measurement

- Consumption data:
  - County-level data on MasterCard purchases.
  - Zipcode-level data on auto purchases.
- Change in housing wealth:  $\Delta \log p_{06-09}^{H,i} * H_{2006}^i$ ,

where  $H^i$  is the value of owner-occupied houses and  $\Delta \log(p^{H,i})$  is the percent change in house prices.

- Concerns about data and measurement?

# Estimation

- OLS (potentially with controls).
- IV using a geography-based estimate of housing supply elasticity from Saiz (2010).
- Concerns about the estimation?

*Notes.* Dependent variable: change in spending 2006–9 (\$000). This table presents coefficients from regressions relating the change in household spending to the change in home value between 2006 and 2009. Both the change variables are in thousands of dollars. All regressions are at the county level. Standard errors are heteroskedasticity robust, clustered at the state level. All regressions are weighted by the number of households in the county. \*\*, \* Coefficient statistically different than 0 at the 1% and 5% confidence levels, respectively.

*Notes.* This table presents coefficients from regressions relating the change in household spending to the change in home value between 2006 and 2009. All regressions are at the ZIP code level. The housing leverage ratio is defined to be the ratio of mortgage and home equity debt to home value in a ZIP code as of 2006. Throughout,  $\Delta$  signifies change in thousands of dollars. Standard errors are heteroskedasticity robust, clustered at the state level. All regressions are weighted by the number of households in a ZIP code. \*\*, \* Coefficient statistically different than 0 at the 1% and 5% confidence levels, respectively.

From: Mian, Rao, and Sufi, “Household Balance Sheets”

## Implications and Discussion

- “the aggregate impact of wealth shocks depends not only on the total wealth lost but also on how these losses are distributed .... [L]everage in combination with asset price shocks can translate into demand-driven recessions.”
- “The drop in value of housing between 2006 and 2009 is equal to \$5.6 trillion .... An MPC of 0.06 implies that the [resulting] drop in consumption ... is equal to \$336 billion,” or about 2.3% of GDP.
  - What is this an estimate of?
  - Concerns?

## V. A LITTLE ABOUT GLS, HETEROSKEDASTICITY- CONSISTENT STANDARD ERRORS, CLUSTERING, AND ALL THAT

# The Big Picture

- We spend much of the course worrying about the possibility that coefficient estimates (or other estimates of economic relationships) may be biased.
- But standard errors can also be biased – sometimes greatly.
- Just as there is no mechanical way to solve the problem of potential bias in point estimates, there is no mechanical way to solve the problem of potential bias in standard errors.

## Basics

- Consider  $Y = X\beta + \varepsilon$ . The standard errors of the OLS estimates of  $\beta$  are the square roots of the diagonal elements of  $(X'X)^{-1}X'\Omega X(X'X)^{-1}$ , where  $\Omega$  is the variance-covariance matrix of  $\varepsilon$ .
- Thus, standard errors can be computed using  $(X'X)^{-1}X'\hat{\Omega}X(X'X)^{-1}$ , where  $\hat{\Omega}$  is an estimate of  $\Omega$ .
- The basic idea of corrected standard errors is to use information from the estimated residuals to construct  $\hat{\Omega}$ .

# The “Original Sin” of Corrected Standard Errors

- Since  $\Omega \equiv E[\varepsilon\varepsilon']$ , it is tempting to estimate  $\Omega$  as  $\hat{\Omega} = \hat{\varepsilon}\hat{\varepsilon}'$ , where  $\hat{\varepsilon}$  is the vector of regression residuals.
- With this choice of a  $\hat{\Omega}$ , our estimated variance-covariance matrix for  $\hat{\beta} - \beta$  is  $(X'X)^{-1}X'\hat{\varepsilon}\hat{\varepsilon}'X(X'X)^{-1}$ .
- We can write this as  $(X'X)^{-1}(X'\hat{\varepsilon})(X'\hat{\varepsilon})'(X'X)^{-1}$ .
- Since  $X'\hat{\varepsilon} = 0$ , this gives us standard errors of zero.
- Oops!

## For More on These Issues

- See the handout.
